Finite dimensionality of $\mathcal{Z}$-boundaries and its consequences

Molly Moran

University of Wisconsin–Milwaukee

Abstract. The rich study of boundaries of CAT(0) and hyperbolic groups led M. Bestvina to formalize the concept of a group boundary by defining a $\mathcal{Z}$-structure on a group. In his original definition, a $\mathcal{Z}$-structure on a group $G$ is a pair of spaces $(\hat{X}, Z)$ where $\hat{X}$ is a compact ER, $Z$ is a $\mathcal{Z}$-set in $\hat{X}$, $G$ acts freely, cocompactly, and properly on $X = \hat{X} - Z$ and the collection of $G$-translates of a compact set in $X$ forms a null sequence in $\hat{X}$. In this setting, $Z$ is finite dimensional. We show that this result can be extended to the case that $\hat{X}$ is an AR, that is when $\hat{X}$ need not be finite dimensional. We also explore results that can be obtained by knowing the $\mathcal{Z}$-boundary is finite dimensional.
